Contact the patient’s doctor right away if you see any of the following symptoms:

- Confusion
- Frequent mood swings
- Memory loss, including forgetting recent events or family members’ names
- Sudden changes in personality or emotional state
- Decreased attention or concentration
- Periods of alertness that come and go throughout the day
- Hallucinations (seeing or hearing things that are not there)
- Insomnia and changes in usual sleep patterns (difficulty falling asleep, staying asleep or changes in usual sleep patterns)
- Slower movements or unusually restless movements
- Changes in speech, such as saying things that don’t make sense

Dementia and Delirium

Dementia and delirium may be particularly difficult to distinguish, and a person may have both. In fact, people with dementia are at higher risk for developing delirium. Dementia is the progressive worsening of memory and other thinking skills due to gradual changes in the brain. The most common cause of dementia is Alzheimer's disease.

Some differences between the symptoms of delirium and dementia include:

- **Onset.** The onset of delirium occurs within a short time (hours to days, perhaps weeks), while dementia usually begins with relatively minor symptoms that gradually worsen over time (months and years).
- **Attention.** The ability to stay focused or maintain attention is significantly affected with delirium. A person in the early stages of dementia remains generally alert.
- **Fluctuation.** The appearance of delirium symptoms can change and vary significantly and frequently throughout the day. While people with dementia have better and worse times of day, their memory and thinking skills stay at a fairly constant level during the course of a day.
